

# ENGG1003 - Tuesday Week 4

## Loose Ends Functions

Brenton Schulz

University of Newcastle

March 16, 2019

# Subscript Notation

- ▶ Last chance to learn that we use:

$$x_1, x_2, x_3, \dots, x_n \quad (1)$$

and

$$x_n = x_{n-1} + x_{n-2} \quad (2)$$

notation because it is the simplest method that gets the point across.

# Subscript Notation

- ▶  $x_n$  means that  $x$  is “some number” and  $n$  is an *integer* value
- ▶  $n$  implies *uniqueness* (ie:  $x_1$  and  $x_2$  can differ)
- ▶  $n$  implies an *order* to the  $x$ 's
- ▶ A formal mathematical statement of the above would be something like:

$$x_n : x \in \mathbb{R} \text{ and } n \in \mathbb{Z} \quad (3)$$

- ▶  $\mathbb{R}$  is the set of real numbers
- ▶  $\mathbb{Z}$  is the set of all integers

# Subscript Notation

- ▶ Without this notation it is *really* hard to write things like:

$$x_n = x_{n-1} + x_{n-2} \quad (4)$$

# Subscript Notation

- ▶ Without this notation it is *really* hard to write things like:

$$x_n = x_{n-1} + x_{n-2} \quad (4)$$

- ▶ If you instead wrote:  
“Calculate a sequence of numbers,  $a, b, c, d, \dots$ ”  
how would you write the equation?

# FOR Loops in C

- ▶ The C FOR loop syntax is:

```
1 for( initial ; condition ; increment ) {  
2     // Loop block  
3 }
```

- ▶ Where:

- ▶ `initial` is a statement executed *once*
- ▶ `condition` is a statement executed and tested *before* every loop iteration
- ▶ `increment` is a statement executed *after* every loop iteration, but *before* the `condition` is tested

# FOR Loops in C

```
1 for( x = 0 ; x < 10 ; x++ ) {  
2     printf("%d\n", x);  
3 }
```

- ▶ Run this code
- ▶ Observe that:
  - ▶ 0 is printed
  - ▶ 10 is **not** printed
  - ▶ x increments automatically

# FOR Example 1 - Factorials

- ▶ Use FOR to count from 2 to our input number
- ▶ Keep a running product as we go

```
BEGIN
  INPUT x
  result = 1
  FOR k = 2 TO x
    result = result * k
  ENDFOR
END
```

- ▶ Is this algorithm robust? What happens if:
  - ▶  $x = -1$
  - ▶  $x = 1$
  - ▶  $x = 0$  (**NB:**  $0! = 1$  because *maths*)

# BREAK Statements

- ▶ Sometimes you want to exit a loop *before* the condition is re-tested
- ▶ The flow-control mechanism for this is a BREAK statement
- ▶ If executed, the loop quits
- ▶ BREAKs typically go inside an IF
- ▶ It adds an extra condition on loop exit placed at any point in the loop

## FOR Example 2

- ▶ Two equivalent ways to implement the  $\cos()$  series from before are:

**NB:**  $|tmp|$  means “absolute value of tmp”.

```
BEGIN
  INPUT x
  sum = 0
  FOR k = 0 to 10
    tmp =  $\frac{(-1)^k x^{2k}}{(2k)!}$ 
    sum = sum + tmp
    IF |tmp| < 1e-6
      BREAK
    ENDIF
  ENDWHILE
END
```

```
BEGIN
  INPUT x
  tmp = 1
  k = 0
  sum = 0
  WHILE (k<10) AND (|tmp|>1e-6)
    tmp =  $\frac{(-1)^k x^{2k}}{(2k)!}$ 
    sum = sum + tmp
    k = k + 1
  ENDWHILE
END
```

# break Statements

- ▶ The example is mildly pointless
  - ▶ In C, the  $|tmp| < 1e - 6$  condition can go in the `for()` statement. In pseudocode it *sort of* can't.
- ▶ It is there to illustrate what `break` does, not explain how to use it
- ▶ As the “experienced engineer” that’s up to you

# FOR Loops in C (Advanced)

- ▶ `for()` syntax allows multiple expressions in the `initial` / `condition` / `increment` sections
- ▶ Separate expressions with commas
- ▶ eg:

```
1 int x, y=10;  
2 for( x = 0 ; x < 10 ; x++, y++ ) {  
3     printf("x: %d y: %d\n", x, y);  
4 }
```

- ▶ This increments both `x` and `y` but only `x` is used in the condition

# Loop continue Statements

- ▶ A `continue` causes execution to jump back to the loop start
- ▶ The *condition* is tested before reentry
- ▶ eg, run this in the Che debugger:

```
1 int x;  
2 for(x = 0; x < 10; x++) {  
3     if(x%2 == 0)  
4         continue;  
5     printf("%d is odd\n");  
6 }
```

- ▶ (Not the best example but gets the point across)

# break and continue

- ▶ Some programmers claim that `break` and `continue` are “naughty”
- ▶ Well, yes, but actually no
- ▶ They *can* make your code needlessly complicated
- ▶ They might make it simpler
- ▶ It is up to you to judge
- ▶ As engineers you shouldn't follow strict rules
- ▶ Always try to choose the best tool for the job

# GOTO

- ▶ There exists a GOTO flow control mechanism
  - ▶ Sometimes also called a *branch*
- ▶ It “jumps” from one line to a different line
  - ▶ An ability some consider to be unnatural
- ▶ It exists for a purpose
- ▶ That purpose does not (typically) exist when writing C code
  - ▶ C *supports* a `goto` statement
  - ▶ It results in “spaghetti code” which is hard to read
  - ▶ Don't use it in ENGG1003
- ▶ You *must* use branch instructions in ELEC1710

# Loose End: Increment Example

```
1 #include <stdio.h>
2 int main() {
3     int x = 0;
4     int y = 0;
5     int z = 0;
6     y = ++x + 10;
7     printf("Pre-increment: %d\n", y);
8     y = z++ + 10;
9     printf("Post-increment: %d\n", y);
10    return 0;
11 }
```

Pre/post-inc/decrements have many applications, more details in coming weeks.

# Binary Nomenclature

- ▶ A data type's value range is a result of the underlying binary storage mechanism
- ▶ A single binary digit is called a *bit*
- ▶ There are 8 bits in a *byte*
- ▶ In programming we use the “power of two” definitions of kB, MB, etc:
  - ▶ 1 kilobyte is  $2^{10} = 1024$  bytes
  - ▶ 1 Megabyte is  $2^{20} = 1048576$  bytes
  - ▶ 1 Gigabyte is  $2^{30} = 1073741824$  bytes
  - ▶ (Advanced) These numbers look better in hex: 0x3FF, 0xFFFFF, etc.

# Binary Nomenclature

- ▶ Observe that kilobyte, Megabyte, Gigabyte, etc use scientific prefixes
- ▶ These *normally* mean a power of 10:
  - ▶ kilo- =  $10^3$
  - ▶ Mega- =  $10^6$
  - ▶ Giga- =  $10^9$
  - ▶ ...etc (see the inside cover of a physics text)
- ▶ Computer science stole these terms and re-defined them

# Binary Nomenclature

- ▶ This has made some people *illogically angry*
- ▶ Instead, we can use a more modern standard:
  - ▶  $2^{10}$  bytes = 1 kibiByte (KiB)
  - ▶  $2^{20}$  bytes = 1 Mebibyte (MiB)
  - ▶  $2^{30}$  bytes = 1 Gibibyte (GiB)
  - ▶ ...etc
- ▶ Generally speaking, KB (etc) implies:
  - ▶ powers of two to *engineers*
  - ▶ powers of ten to *marketing*
    - ▶ The number is smaller
    - ▶ Hard drive manufacturers, ISPs, etc like this

# Unambiguous Integer Data Types

- ▶ Because the standard `int` and `long` data types don't have fixed size unambiguous types exist
- ▶ Under OnlineGDB (ie: Linux with `gcc`) these are defined in `stdint.h` (`#include` it)
- ▶ You will see them used commonly in embedded systems programming (eg: Arduino code)
- ▶ The types are:
  - ▶ `int8_t`
  - ▶ `uint8_t`
  - ▶ `int16_t`
  - ▶ `...etc`

# Code Blocks in C

- ▶ Semi-revision:
- ▶ The curly braces `{ }` encompass a *block*
- ▶ You have used these with `if()` and `while()`
- ▶ They define the set of lines executed inside the `if()` or `while()`

# Code Blocks in C

- ▶ You can place blocks anywhere you like
- ▶ Nothing wrong with:

```
1 int main() {  
2     int x;  
3     {  
4         printf("%d\n", x);  
5     }  
6     return 0;  
7 }
```

- ▶ This just places the `printf()` ; inside a block
- ▶ It doesn't do anything useful, but...

# Variable Scope

- ▶ A variable's "existence" is limited to the block where it is declared
  - ▶ Plus any blocks within that one
- ▶ Example this code won't compile:

```
1 #include <stdio.h>
2 int main() {
3     int x = 2;
4     if(x == 2) {
5         int k;
6         k = 2*x;
7     }
8     printf("%d\n", k);
9     return 0;
10 }
```

# Variable Scope

- ▶ Note that `k` was declared inside the `if()`
- ▶ That means that it no longer exists when the `if()` has finished
- ▶ This generates a compiler error
- ▶ It frees up some RAM
- ▶ It also lets the variable's name be reused elsewhere
  - ▶ This can be *really* confusing. Be careful.

# Functions

- ▶ A *function* is a block of code which can be *called* multiple times, from multiple places
- ▶ They are used when you want the same block of code to execute in many places throughout your code
- ▶ A function requires:
  - ▶ A name
  - ▶ (optional) A *return value*
  - ▶ (optional) One or more *arguments*

# Functions in Mathematics

- ▶ In mathematics you saw functions written as:

$$y = f(x)$$

- ▶ Here, the function is called  $f$ , takes an argument of  $x$  and returns a value which is given to  $y$
- ▶ C and pure mathematics have these general ideas in common

# Functions in Mathematics

- ▶ In mathematics you saw functions written as:

$$y = f(x)$$

- ▶ Here, the function is called  $f$ , takes an argument of  $x$  and returns a value which is given to  $y$
- ▶ C and pure mathematics have these general ideas in common
- ▶ The similarities stop there

# Function Examples

- ▶ So far, some of you have used *library functions*
- ▶ These are functions which are pre-existing within the compiler (and its libraries)
- ▶ I have shown you:
  - ▶ `scanf()` ;
  - ▶ `printf()` ;
  - ▶ `rand()` ;

# Function Syntax

- ▶ Writing `rand()` ; in you code is *calling* the function
- ▶ The program execution “jumps” into the function’s code, executes it, then jumps back
- ▶ Function call syntax is:  
`[return value] = name( [arguments] )`
- ▶ Not all functions take arguments
- ▶ You may ignore the return value

# Function Examples

## ▶ Example 1:

```
1 x = rand();
```

- ▶ rand is the function name
- ▶ It returns a “random” number
- ▶ The return value is allocated to x
- ▶ It doesn't take an argument

# Function Examples

## ▶ Example 1:

```
1 x = rand();
```

- ▶ `rand` is the function name
- ▶ It returns a “random” number
- ▶ The return value is allocated to `x`
- ▶ It doesn't take an argument

## ▶ Example 2:

```
1 y = sqrtf(x);
```

- ▶ `sqrtf` is the function name
- ▶ `x` is the argument
- ▶ It returns the square root of `x`
- ▶ The return value is allocated to `y`

# Functions

- ▶ Function arguments and return values have pre-defined data types

# Functions

- ▶ Function arguments and return values have pre-defined data types
- ▶ Example from documentation
  - ▶ `int rand(void);`
    - ▶ The return value is an `int`
    - ▶ The argument is type `void`
    - ▶ This just means there aren't any

# Functions

- ▶ Function arguments and return values have pre-defined data types
- ▶ Example from documentation
  - ▶ `int rand(void);`
    - ▶ The return value is an `int`
    - ▶ The argument is type `void`
    - ▶ This just means there aren't any
  - ▶ `float sqrtf(float x);`
    - ▶ The return value is a `float`
    - ▶ The argument is a `float`
    - ▶ Argument is called `x` in documentation but that is irrelevant

# Return Values (an Engineer's View)

- ▶ The function's *return value* is the number a function gets “replaced with” in a line of code

# Return Values (an Engineer's View)

- ▶ The function's *return value* is the number a function gets “replaced with” in a line of code
- ▶ Function return values, variables, and literals can all be used in the same places:
  - ▶ In arithmetic
  - ▶ In conditions
  - ▶ As arguments to other functions

# Return Values (an Engineer's View)

- ▶ The function's *return value* is the number a function gets “replaced with” in a line of code
- ▶ Function return values, variables, and literals can all be used in the same places:
  - ▶ In arithmetic
  - ▶ In conditions
  - ▶ As arguments to other functions
- ▶ The C standard is *very* specific about what return values are but I will be informal for now
  - ▶ Technically, for example, an expression like  $x=y+5.0$ ; also has a “return value” equal to the value allocated to  $x$

# Return Values

- ▶ I use functions from `math.h` in these examples, we'll cover them in a few mins

# Return Values

- ▶ I use functions from `math.h` in these examples, we'll cover them in a few mins
- ▶ The following are all valid:
  - ▶ `x = rand();`
  - ▶ `printf("%f\n", sin(y));`
  - ▶ `if( (rand()%6) < 2)`
  - ▶ `while( sin(x) < 0 )`

# Return Values

- ▶ I use functions from `math.h` in these examples, we'll cover them in a few mins
- ▶ The following are all valid:
  - ▶ `x = rand();`
  - ▶ `printf("%f\n", sin(y));`
  - ▶ `if( (rand()%6) < 2)`
  - ▶ `while( sin(x) < 0 )`
  - ▶ This next one is complicated...

# Return Values

- ▶ I use functions from `math.h` in these examples, we'll cover them in a few mins
- ▶ The following are all valid:
  - ▶ `x = rand();`
  - ▶ `printf("%f\n", sin(y));`
  - ▶ `if( (rand()%6) < 2)`
  - ▶ `while( sin(x) < 0 )`
  - ▶ This next one is complicated...
  - ▶ `x = sin((double)rand());`

# Return Values

- ▶ I use functions from `math.h` in these examples, we'll cover them in a few mins
- ▶ The following are all valid:
  - ▶ `x = rand();`
  - ▶ `printf("%f\n", sin(y));`
  - ▶ `if( (rand()%6) < 2)`
  - ▶ `while( sin(x) < 0 )`
  - ▶ This next one is complicated...
  - ▶ `x = sin((double)rand());`
    - ▶ Generates a random integer, casts to `double`, uses that number as an argument to the `sin()` function

# Using Functions

- ▶ (semi-revision)
- ▶ Before you use a function you must:
  - ▶ Read the documentation
  - ▶ `#include` the correct header file
  - ▶ Add the correct library to the compiler options
    - ▶ In C we've done this for the maths library
    - ▶ `stdio` and `stdlib` are always there
  - ▶ Be aware of the data types
    - ▶ Do you need any type casting?
    - ▶ Are you using the correct function?

# Maths Functions

- ▶ Since some of you have already used them, lets learn about the maths library...
- ▶ It includes functions for:
  - ▶ Trigonometry
  - ▶ Exponentials (base e) & logarithms (base e and 10)
  - ▶ Exponents
  - ▶ Rounding (`floor()`; & `ceil()`;) )
  - ▶ Floating point modulus (`fmod()`;) )
  - ▶ Square roots
  - ▶ Maybe others?

# Maths Functions

- ▶ There are typically *different* functions for `float` and `double`
- ▶ This can have a huge speed impact
- ▶ Get in the habit of using the right ones!
- ▶ `float` maths functions typically end in 'f'
  - ▶ `cosf()` ;
  - ▶ `sqrtf()` ;
  - ▶ `atanf()` ;
  - ▶ ...etc
- ▶ `double` maths functions don't end in 'f'
  - ▶ `cos()` ;
  - ▶ `log()` ;

# Maths Functions

- ▶ Math functions are written by mathematicians
  - ▶ All angles are in radians

# Maths Functions

- ▶ Math functions are written by mathematicians
  - ▶ All angles are in radians
  - ▶  $\log()$  ; is  $\log_e$ 
    - ▶  $\log_{10}()$  ; is  $\log_{10}$
    - ▶  $\log_2()$  ; is  $\log_2$

# Maths Functions

- ▶ Math functions are written by mathematicians
  - ▶ All angles are in radians
  - ▶  $\log()$  ; is  $\log_e$ 
    - ▶  $\log_{10}()$  ; is  $\log_{10}$
    - ▶  $\log_2()$  ; is  $\log_2$
  - ▶ Inverse trig functions are called “arcus functions”
    - ▶  $\sin^{-1}$  is  $\text{asin}()$  ;
    - ▶  $\cos^{-1}$  is  $\text{acos}()$  ;
    - ▶  $\tan^{-1}$  is  $\text{atan}()$  ;

# Maths Functions

- ▶ Math functions are written by mathematicians
  - ▶ All angles are in radians
  - ▶  $\log()$  ; is  $\log_e$ 
    - ▶  $\log_{10}()$  ; is  $\log_{10}$
    - ▶  $\log_2()$  ; is  $\log_2$
  - ▶ Inverse trig functions are called “arcus functions”
    - ▶  $\sin^{-1}$  is  $\text{asin}()$  ;
    - ▶  $\cos^{-1}$  is  $\text{acos}()$  ;
    - ▶  $\tan^{-1}$  is  $\text{atan}()$  ;
  - ▶ The “4 quadrant” arctan function is  $\text{atan2}()$  ;
    - ▶  $\text{atan}(x)$  ; returns  $[0, \pi]$
    - ▶  $\text{atan2}(x, y)$  ; returns  $[-\pi, \pi]$  depending on the quadrant of the point  $x, y$
    - ▶ Very useful for polar to Cartesian coordinate transforms (probably beyond 1st semester 1st year)

# Example - Quadratic Equation

Write a C program which uses the standard library function `sqrtf()` ; as part of the calculations required to produce solutions to a quadratic equation:

$$ax^2 + bx + c = 0 \quad (5)$$

using

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \quad (6)$$

...do it live in Che
